(54) Abstract Title

Pharmaceutical composition for regressive behavioural disease

(57) The invention provides a method for the diagnosis of regressive behavioural disease (RBD) from a body derived sample, which method comprises performing an assay for persistent MMR infection in said sample. The invention also provides a pharmaceutical composition for the treatment of RBD which comprises a soluble dialysed leucocyte extract of an MMR antigen specific transfer factor formed by dialyses at a molecular weight cut-off of 12,500 in a pharmaceutically acceptable carrier or diluent therefor.

#### PHARMACEUTICAL COMPOSITION FOR RBD

The present invention relates to a pharmaceutical or therapeutic composition for the treatment of regressive 5 behavioural disease (RBD)(also referred to as "Regressive Developmental Disorder") or autism.

In my earlier Patent Application No. WO 96/30544 I have described how persistent measles virus infection whether of a wild type or vaccine mediated is the origin of some forms 10 of IBD.

This is at present no cure for autism; sufferers have to live in a silent world of their own unable to communicate with the rest of the world.

I have now discovered a combined vaccine/therapeutic 15 agent which is not only most probably safer to administer to children and others by way of vaccination/immunisation, but which also can be used to treat RBD whether as a complete cure or to alleviate symptoms.

As disclosed in my earlier patent application Crohn's 20 Disease is most probably caused by a failure of the body to completely eliminate the measles virus, probably because of the failure of the initial dosage of virus to illicit a full immune response, which in turn allows the remaining virus to collect at various sites in the body particularly in the small 25 intestine and colon thereby causing the granulomatous vasculitis associated with Crohn's disease.

Although the mechanism of virus infection is not fully elucidated, it seems likely at present that the mechanism which gives rise to gut granuloma is as follows:-

30

Following an incomplete immune response to an attenuated virus challenge in early life, or indeed less often a wild type infection, measles virus collects in the wall of the gut and particularly in the capillaries supplying blood thereto. At some point, often when a patient is between 20 to 30 years 35 old, this induces a vasculitis which in turn causes necrosis of the overlying epithelium of the gut. I have previously shown that measles virus is present in these granulomatous lesions. It appears that for some reason lymphocytes which bind to the measles virus site fail to eliminate the virus so identified. What is needed therefore is a system for "switching on" the destruct mechanisms of the bound 1 lymphocytes which appear to be disenabled by the persistent measles virus particles.

. I have now found that regressive behavioural disorder (RBD) in children is associated with measles, mumps and rubella (MMR) vaccination. Although it is yet to be 10 established which element, if only one of MMR, for example measles virus, is directly implicated, histological and serological examination of a sample of children who exhibited RBD showed lesions in the gut indicative of the problems which arise in IBD and Crohn's Disease. Further I have reviewed a 15 cohort of children who following a period of apparent normality have lost acquired skills including those of communication. These children all have gastrointestinal symptoms including abdominal pain, diarrhoea, and in some cases food intolerance. It is significant that this syndrome 20 only appeared with the introduction of the polyvalent MMR vaccine in 1988 rather than with the monovalent measles vaccine introduced in 1968. This indicates that MMR is responsible for this condition rather than just the measles virus and that accordingly a transfer factor (vide infra) 25 specific for the components other than the measles virus in MMR maybe required.

In these children the mean interval from exposure to the MMR vaccine to the development of first behavioural symptom was six days, indicating a strong temporal association with exposure to the vaccine. Measles virus nucleocapsid protein antigen has been identified with the follicular dendritic cells in areas of lymphoid nodular hyperplasia in the affected intestine, further implicating a causal role for measles virus in this disease. These children exhibit immunodeficiencies associated with reduced numbers of circulating T lymphocytes. Specific boosting of antiviral immunity in these children could, therefore, be expected to be of therapeutic benefit.

intestine, further implicating a causal role for measles virus These children exhibit immunodeficiencies in this disease. associated with reduced numbers of circulating T lymphocytes. Specific boosting of antiviral immunity in these children 5 could, therefore, be expected to be of therapeutic benefit.

Adoptive transfer of non-antigen-specific cell mediated immunity in humans was first demonstrated by Lawrence in Proc.Soc.Biol.Med 1949; 71; 516. This opened a new avenue of research that has led to an increased understanding of the 10 basic immune mechanisms and to the development of many forms of immunomodulant therapy. Lawrence originally showed that transfer of intact, viable, lymphocytes from a normal tuberculin skin test-positive donor to a skin test-negative recipient, resulted in conversion ("transfer") 15 recipient to skin test-positivity.

Lawrence further demonstrated that delayed cutaneous hypersensitivity (DH) responsiveness could be transferred by a soluble, dialysed leucocyte extract (DLE). He termed the factor responsible for this phenomenon "transfer factor" (TF). 20 (TF) could transfer (DH) of a given specificity from a normal skin test-positive donor to a skin test-negative recipient. Moreover, within 6 months, leucocytes from the primary recipient could transfer specific (DH) to a previously skin test-negative secondary recipient.

In addition to transferring non-antigen-specific skin test positivity, DLE preparations containing TF can also initiate other non-antigen-specific cell mediated immune reactions including induction of cytokines such as macrophage migration inhibitory factor (MIF) and leucocyte migration 30 inhibitory factor (LIF). The ability of TF to stimulate LIF production forms the basis for assessing, in vitro, the potency of non-antigen-specific TF.

25

Despite Lawrence's work the considerable potential for TF as a therapeutic agent capable of transferring specific 35 immunity to individuals who lacked such immunity was not recognised until about 1990. It has recently been used therefore in treatments for chickenpox, herpes virus infections, liver disease and in the treatment of HIV.

Generally human, mouse and bovine TF are small molecules of approximately 3500 to 6000 Daltons. TF is heat labile but cold stable; biological activity remains unimpaired after several years of storage at -20°C to -70°C. Most studies of the effects of enzymes on the antigen-specific biological activity of TF indicate that it is composed of RNA bases attached to small peptides of at least 8 amino acids. If as seems likely each TF is antigen specific then individual TF's may differ structurally in a manner similar to the subtle variations in antigen-binding sites at the hypervariable region of immunoglobulins or in the T cell receptor for antigens. This specificity is supported by the fact that TF specific for, for example, PPD antigen binds only PPD and no other antigen.

The mechanisms whereby TF participate in the cellmediated immune response are simply not known. One hypothesis
is that TF forms part of the T-lymphocyte receptor (TCR) for
antigen and that its presence may be necessary for T cell
activation. However, further supportive data are required
that are compatible first with the activity of TF in the
normal T cell mediated immune response and secondly with the
ability of TF to transfer such immunity to a previously nonresponsive recipient in an antigen-specific fashion.

In an antigen-responsive subject a small number of T cells bearing receptors for a given antigen are continually present. These membrane receptor sites probably include the TF moiety. Specific antigen binding to the appropriate receptor probably initiates production and the release of more TF which then binds to immunologically uncommitted T lymphocytes rendering them antigen-sensitive and responsive.

Similarly, in transfer of immunity to the non-responsive host, exogenous TF most probably binds to immunologically "virgin" cells. This binding may induce T cell receptor expression with the resulting complex of antigen-specific TF and the T cell receptor forming the specific antigen receptor

vivo however DLE enhances graft rejection and augments lectindependant antibody dependent cellular cytotoxicity. This wide variety of effects of crude DLE reflects the activities of its many different moieties including non-specific adjuvant or 5 inhibitory functions. Antigen-specific properties due to the TF moiety within the DLE include the ability to confer upon non-responsive lymphocytes the ability to react with the relevant antigen in vivo to produce lymphokines in vitro and to enhance antigen-specific T cells cytoxicity against tumour 10 antigens by previously non-responsive cytotoxic cells.

DLE-TF is usually administered by subcutaneous intramuscular injection, although oral administration appears equally effective. It can also be given intravenously or by suppository or by incorporation into liposomes to prolong its about Nothing is known activity. 15 biological \_\_\_\_ pharmakinetics.

Further DLE-TF is remarkably free from adverse side effects. Given intramuscularly or subcutaneously an injection may cause pain at the injection site for 10 to 20 minutes and 20 low-grade transient pyrexia may occur but no other significant problems have occurred. However severe pain can be induced at the site of primary or metastatic lesions caused by tumour necrosis when used in cancer therapy.

According therefore to a first aspect of the invention 25 there is provided a method for the diagnosis of RBD from a body derived sample, which method comprises performing an assay for persistent MMR infection in said sample. thus may be performed for the detection of wild or vaccine mediated measles virus.

30

According to a second aspect of the invention there is provided a method for the treatment of Regressive Behavioural Disease (RBD) which comprises administering to the subject suffering the effects of an MMR virus mediated RBD disease a soluble dialysed leucocyte extract comprising an antigen 35 specific transfer factor (TF) formed by the dialysis of a virus specific lymphocytes to a molecular cut off of 12,500 in a pharmaceutically acceptable carrier of diluent therefor.

In the third aspect of the invention there is provided a pharmaceutical composition for the treatment of RBD which comprises a soluble dialysed leucocyte extract comprising an MMR antigen specific transfer factor formed by the dialysis of a virus specific lymphocytes to a molecular cut off of 12,500 in a pharmaceutically acceptable carrier or diluent therefor.

The TF factor is particularly significant when directed to the measles virus alone but a TF factor for MMR, which is 10 taken to include live attenuated measles vaccine virus, measles virus, mumps vaccine virus and rubella vaccine virus, and wild strains of the aforementioned viruses, or for the other components of MMR (mumps and rubella) is also useful for RBD.

The compositions may be particularly adapted for use as a vaccine/immunisation or for use as therapy for RBD. Preferably the transfer factor is a molecule of approximately 3,500 to 6000 Daltons which is cold stable. The compositions may be adapted for subcutaneous, intra muscular or intravenous injection or for administration by the oral route, by suppository or by incorporation into administrable liposomes.

The invention will now be described, by way of illustration only, with reference to the following examples and the accompanying figures.

25

Figures 1A to 1D show a comparison of the gene sequence of the majority consequences sequence (MCS\*) of the measles virus H region using all wild-type and vaccine strain sequences from GenEMBL on 1 June 1994 with the gene sequence of the vaccine, sporadic wild strains, measles virus H regions isolated from patients with Crohn's disease, ulcerative colitis, autism, inflammatory bowel disease with SSPE strains. The complete sequence between base 8393 and 8550 was determined for each of the genes but only the mutations in them are shown in Figure 1.

#### Example 1 - Preparation of DLE

inflammatory bowel disease with SSPE strains. The complete sequence between base 8393 and 8550 was determined for each of the genes but only the mutations in them are shown in Figure 1.

#### Example 1 - Preparation of DLE

Measles virus-specific TF is made from lymphocytes of BALB/c mice immunised by live or killed virus or an antigen derived from such a measles virus. Isolated cells are freeze-10 thawed and, following micropore filtration the filtrate is added to an immunologically virgin human lumphoblastoid cell One cell is serially expanded 10-fold with killed measles virus and interleukin-2, to a billion cells. Measles virus-specific TF preparations are made from this expanded Cell lysis, dialysis using a 12,500 15 cell population. molecular weight cut-off and a series of concentration procedures results in a TF preparation containing TF and lysozyme. The molecular weight of each preparation used is between 1,800 and 12,000. Appropriate biological markers eg. 20 lysozyme (MW 11,000), horse myoglobin (MW 17.7 KD) and human antibody light chains (MW 22 KD) are used as controls to ensure both the recovery of TF and absence of materials greater than 12,000 MW in the final preparation (viruses are hundreds of millions in molecular weight, and reverse 25 transcriptase of retroviruses is 59 KD). The TF preparation is standardised for potency (vide infra). The ability of TF to stimulate further TF production, and the cross-species reactivity of TF are subsequently exploited in order to produce large amounts of concentrated TF at low cost. 30 is achieved by injecting the TF preparation into pregnant goats 3 times prior to delivery. Colostrums are collected during the first 3 days post-delivery and TF preparations were made from these by micropore filtration excluding molecules >12,500 mol wt. Following freeze thawing and lyophilising x 35 3 the preparation is tested for potency as described below and standardised at 200 South Carolina units/ml.

Example 2 - In vitro determination of potency.

LIF production in response to the defined specific antigen, is measured by the direct assay for inhibition of random leucocyte migration in agarose. Briefly, Leucocytes are incubated with medium 199 only (control) or with medium 5 plus test antigen at 37°C. During this incubation period the neutrophils randomly migrate out of the application weeks to form a circular zone of cells. Responsiveness to antigen is expressed as a migration index (MI). If lymphocytes respond normally to the antigenic challenge, LIF is liberated and 10 prevents or reduces the normal neutrophil random migration. The test is used extensively in the diagnosis of antigen specific cell mediated immune defects. The addition of DLE to this system has two potential effects: firstly, an antigenindependent inhibition of migration at low concentrations of secondly, and antigen-specific induction enhancements of LIF production at lower concentrations of extract.

DLE-TF potency is determined by taking aliquots of target cells (peripheral blood leucocytes) from 3 normal donors, 20 previously shown to be unresponsive to the test antigen by Cells are incubated with either 1) medium alone, 2) medium plus antigen, 3) DKE (at 10 serial dilutions) in medium 4, and 4) DLE (in the same 10 serial dilutions) plus antigen plus medium for 30 minutes at 37°C in a humidified incubator. 25 After 18 hours, migration indices are determined as follows: MIA-antigen dependent LMI produced by non-TF components; and  ${
m MI_{B}} ext{-antigen}$  dependent LMI induced by LIF released from T lymphocytes newly sensitised by TF in the presence of specific An MIB value <0.90 indicates meaningful antigenantigen. 30 dependent LMI. All concentrations (150ul) are tested in 6 replicate cultures. If 40ul provide an MIB of 0.90, then 1ml of this DLE contains 25 S.C. potency units.

#### Dose regimen

One to up to ten, but preferably three or four capsules (20 S.C. units per capsule) per day should be ingested.

#### Laboratory monitoring of clinical response

It is important to note that there is a marked interindividual response to any particular batch of DLE-TF.

- 5 Patients are monitored immunologically by:
  - the ability of DLE-TF MV to restore cutaneous hypersensitivity as measured by the Merieux skin test.
  - levels of circulating CD8+CD38+DR+cytotoxic T cells,
     measured by flow cytometery.
- 10 lymphocyte migration inhibition, as described above.

Another valuable immunological test is antigen-specific T cell cytotoxicity. The use of this test for determination of measles virus-specific cytotoxicity has been described by 15 Fooks et al in virology 1995, 210, 456 to 465. Purified Tlymphocytes are cultured with measles virus infected Raji (B cell line labelled with radiolabelled chromium cell) The specific uninfected cells are used as controls. cytotoxicity of the lymphocytes results in lysis of the 20 infected cells and release of radioisotope from cells of other tumour types. Addition of DLE-TF derived from a donor proven by this test to be responsive to the relevant antigen, enhances the specific cytotoxicity of the lymphocytes in a dose-dependent manner.

25 The results of Examples 1 and 2 show anecdotally that TF is an effective agent for the treatment of IBD and as a vaccine for measles virus.

#### Example 3

30

In order to investigate a consecutive series of children for a new syndrome comprising chronic enterocolitis and regressive behavioural disorder (RBD) 12 children with a mean age of 6 years, range 3 to 10, all but one of whom were male, were referred with a history of achievement of normal developmental milestones followed by loss of acquired skills including language along with bowel symptoms, diarrhoea, abdominal pain and in some cases food intolerance all associated with the presence of MMR viruses in the gut.

The children underwent gastroenterolgical, neurological and developmental assessment including review of prospective in developmental records. Under sedation, ileo-colonoscopy and biopsy, MRI, EEG, and lumbar puncture were performed. Barium follow-through was undertaken where possible. Chemistry, haematology and immunology profiles were examined.

10

It was found that the onset of behavioural symptoms were associated with MMR (mumps, measles and rubella vaccinations) in 8 of the 12 children and with measles infections one child and otitis media in another. All 12 children had significant 15 intestinal pathology ranging from lymphoid nodular hyperplasia to aphthoid ulceration. Histology revealed patch chronic inflammation in the colon in 11 cases and reactive ileal lymphoid hyperplasia in 7 cases, but no granulomas. had ileal lymphoid nodular hyperplasia alone diagnosed on 20 barium follow-through. Behaviourally, they all formed a heterogeneous diagnostic group which included autism (9/12), disinteragrative psychosis (1/12) and possible viral/vaccinial encephalitis (2/12). All the children exhibited features of severe developmental regression. 25 Clinically they had no focal neurological abnormalities and MRI and EEG studies were within normal limited. summarise the above endoscopic, histological and neuropsychiatric diagnosis.

30 Accordingly a significant gastrointestinal pathology has been identified in association with behavioural regression in a selected group of previously, apparently normal children. In the majority there is therefore a clear association with possible environmental triggers.

The persistence of measles virus infection and the immunological status of children with a combination of regressive developmental disorder, ileo-colonic lymphoid nodular hyperplasia and non-specific colitis was investigated.

#### Detection of viral antigen

5

Vero (African green monkey kidney) cells were cultured and infected with HU-2 strain measles. After two days, when the 10 characteristic syncytial cytopathic effect was observed, the cell layers were washed with PBS and harvested using a cell The cells were disrupted using a sonicator, in 1ml lysis buffer (8M urea, 150mM  $\beta$ -mercaptoethanol, 50mM Tris-HCl pH 7.5) on ice, at a concentration of 10<sup>7</sup> cells/ml. 15 Undisrupted cells and cell debris were removed centrifugation (1500 x g, 20 min,  $4^{\circ}$ C). Uninfected Vero cells were cultured and lysed in an identical manner to the infected cells and used as controls.

20  $4\mu l$  of each cell lysate was fractionated by SDS-PAGE and transferred to a nitrocellulose membrane in a tank transfer system at 200mA for 16h. 1.4 $\mu$ g of purified measles virus nucleocapsid protein expressed in Sf9 cells served as a positive control. Transfer of equal amounts of protein was 25 confirmed by Ponceau staining. Following saturation in blocking buffer (phosphate buffered saline [PBS], 0.1% v/v Tween-20 containing 5% w/v skimmed milk powder) for 1 h at room temperature, the filters were incubated with either RAd68 or preimmune serum at a 1:5 000 dilution of blocking 30 buffer. After three washes in PBST (PBS, 0.1% v/v Tween-20) each for 10min, the membranes were incubated in a 1:1 000 dilution of second antibody (horseradish peroxidase-conjugated anti-mouse immunoglobulins) in PBST for 1 h Following a further three washes in PBST each temperature. 35 for 10min, the immunoassay was developed using the ECL detection system according to the manufacturer's instructions. Western blot analysis was also performed, in an identical

manner, on protein extracted from normal human intestinal tissue.

The strong immunoreactivity of RAd68\* with the measles N-protein was observed. No signal was obtained using either the corresponding preimmune serum or following application of RAd68\* to the protein extract from uninfected cells. Western blot analysis RAd68\* on extracted normal human intestine gave no signal. This confirms the specificity of the measles virus antisera to be used on affected intestinal tissues.

#### Immunocytochemistry

The specificity of RAd68<sup>+</sup> for measles virus was examined further by immunocytochemistry using mumps virus - a related paramyxovirus - and rubella virus as controls. Measles virus (HU-2 strain), mumps virus (Urabe strain), and rubella virus infected Vero cells were prepared separately and processed for immunocytochemistry using an immunoperoxidase technique as described previously. Uninfected Vero cells were used as negative controls of RAd68<sup>+</sup> and the primary mumps and rubella virus antibodies.

Since the RAd68 had been raised in an adenovirus type-5 25 construct, the likelihood of cross-reactivity with adenovirus antigens was examined. When RAd68 was applied to either adenovirus-infected intestinal tissue or a commercial preparation of HeLa cells infected with adenovirus-type 5 it produced specific staining in both. In view of this cross-30 reactivity, parallel sections from the biopsy series of 12 children were immunostained for both measles virus N-protein and adenovirus, the latter using a commercial adenovirus antibody that identified the relevant type-5 strain, in order to discriminate the presence of these different virus antigens In addition, murine antiserum raised in an 35 within tissues. identical manner to RAd68 to but without the measles virus Ngene (RAd68), was applied to both measles and adenovirus

infected cells and tissues. Negative controls also included sections incubated with normal mouse serum at a dilution of 1:300, based upon measurement of the total serum protein concentration and calculation of the estimated IgG fraction.

5 Sections which were developed following omission of the primary measles virus antiserum served as a further control.

When RAd68 was applied to sections of measles virus infected and uninfected Vero cells positive cytoplasmic staining was observed in infected cells only in areas of characteristic syncytial cytopathic effect. No staining was seen when either RAd68 was omitted, when sections were incubated with the pre-immune mouse serum or when RAd68 genes were added in place of RAd68.

15

In both mumps and rubella virus infected cells, positive cytoplasmic staining was observed following addition of the specific primary antibody. Conversely, no staining was observed with either RAd68 or following omission of the respective primary antibodies. RAd68 and RAd68 applied to HeLa cells infected with adenovirus type-5 produced positive nuclear staining, consistent with the origin of the vector used to raise the antisera.

## 25 Adsorption of RAd68\*

Rad68\* was applied in triplicate to wells of 96 well plates prepared commercially for ELISA using lysed measles virus infected cells as the antigen. The wells were incubated for 1 hour then the supernatants were transferred to new wells. This procedure was repeated 5 times. The resulting supernatants were applied to measles virus infected cells and tissues (brain - SSPE(subacute sclerosing panencephalitis), gut) and developed as described above. RAd68\*, processed similarly on control wells containing uninfected cells lysates, were applied to serial tissue sections for comparison.

Following absorption of RAd68<sup>+</sup> on whole measles antigen, the signal was greatly reduced in measles virus infected tissue, both in terms of numbers of positively stained cells and staining intensity, compared with RAd68<sup>+</sup> adsorbed in control wells containing uninfected cells. The latter produced a strongly positive signal in measles virus infected tissue which was identical to the unadsorbed antiserum.

#### Tissue Studies

10

Intestinal biopsies from the 12 children were taken. This included single terminal ileal biopsies from 9 children and a total of 52 colonic biopsies including samples from rectum through to caecum from all 12 children. Serial sections from each biopsy were stained immunohistochemically for the following viruses: measles, rubella, Herpes simplex, mumps, adenovirus and human immunodeficiency virus (HIV). Control tissues included sections developed either following omission of the primary antibody, or with the corresponding pre-immune serum or immunoglobulin fraction.

Positive controls for measles virus infection included postmortem tissues from one case of SSPE, one case of measles inclusion body encephalitis (MIBE), and tissue from an acutely infected small intestine of in an African child with AIDS who was suffering from measles pneumonia.

Control intestinal biopsy samples were obtained from 10 children in whom the initial colonoscopic findings were 30 reported as normal. A total of 70 sections were studied, including those from ileum, caecum, colon and rectum.

In addition, 10 archival age-matched terminal ileal biopsies were studied from children with Crohn's disease, selected consecutively on the basis that the haematoxylin and eosin stained section contained at least one lymphoid follicle with its associated germinal centre.

Lymph node biopsy specimens from 6 patients with lymphadenopathy and AIDS were also immunostained with RAd68<sup>+</sup> and primary HIV antibody.

5

The ileal biopsy sections from 5 children were examined by double immunohistochemical labelling for measles virus-N protein and follicular dendritic cells using CD21 monoclonal antibody. The sections were incubated with normal goat serum 10 for 20 min followed by application of measles virus primary antibody (RAd68') overnight at 4°C. Sections were washed three times for 5 minutes in Tris-buffered saline (TBS). Thereafter biotinylated goat-anti rabbit antibody was applied at 1:200 dilution plus normal human serum for 30 min at room 15 temperature. A blocking murine monoclonal anti-Pneumocystis carinii antibody was then applied at a dilution of 1:20 for 60 min, followed by goat-anti mouse Fab fraction at 1:20 dilution for 30 min at room temperature. The development step consisted of streptavidin ABC at a 1:1:200 20 dilution for 30 min at room temperature followed by addition of diaminobenzidine. Sections were then microwaved for 20 min in citrate buffer at pH 6.0 followed by application of monoclonal CD 21 at a dilution of 1:20 for 60 min at room temperature. After washing three times in TBS, alkaline 25 phosphatase conjugated sheep anti-mouse monoclonal antibody was added for 75 min at room temperature, and the sections were finally developed with Fast Red. Controls included omission of either primary antibody, both primary antibodies, or incubation with the blocking murine monoclonal anti-P. 30 carinii antibody alone.

30 carinii antibody alone.

MIBE and SSPE serve as a useful comparison for examining measles virus antibody specificity. Both represent brain tissue that is persistently infected with measles virus, although the pattern of staining is characteristic in the two conditions. In sections of MIBE, RAd68 produced positive staining in cells containing distinctive, large nuclear

inclusion bodies. In SSPE, staining for measles virus was detected in inflammatory foci, specifically in neurones, microglia and endothelial cells that did not exhibit the characteristic cytopathic change of MIBE.

5

( )

Hence, RAd68<sup>+</sup> distinguished the pattern of measles virus immunostaining between the two diseases, and no staining was seen on brain sections either from which the primary antibody had been omitted or RAd68<sup>+</sup> substituted for RAd68<sup>+</sup>.

10

In acute measles virus infection of the small intestine, staining was detected in discrete foci of epithelial cells in 2 of 4 Peyer's patches, and in occasional lymphocytes and endothelial-like cells within the lamina propria and submucosa.

In both the measles virus and adenovirus infected intestinal tissues, infected cells exhibited cytopathic vacuolation that was not seen in adjacent cells which presumably, were not infected.

20

In the 9 terminal ileal biopsies from children with intestinal pathology and associated behaviour disorder, 7 contained a complete lymphoid follicle with its associated germinal centre. In 2 cases, where these structures had been previously identified in haematoxylin and eosin-stained sections, resulting in them having been cut out due to multiple sampling.

Positive measles virus immunostaining was identified using 30 RAd68<sup>+</sup> in 5 of the 7 cases. Positive staining was confined exclusively to the germinal centres of lymphoid follicles. Staining was punctate, and its distribution appeared to follow the cytoplasm or cytoplasmic membrane of cells with an extensive cytoplasm. An identical pattern of staining was observed in HIV infected lymphocytes stained with HIV primary antibodies.

Positive staining for measles was detected in children for whom the onset of symptoms had been associated with a clinical episode of measles in 1 case (but previously vaccinated with MMR) and MMR in 3 cases. In the case of the fifth positive child, no exposure had been noted: onset of behavioural symptoms started at 18 months and his only recorded exposure to either measles or rubella had been as MMR at 16 months of age.

10 Double immunostaining of ileal biopsies with RAd68 and CD21 confirmed that the measles virus signal localised to follicular dendritic cells. A similar pattern of staining was seen in the specimen of small intestine that was acutely infected with the measles virus.

Out of a total of 52 colonic biopsies, 5 individual biopsies from different children showed lymphoid follicles, all of which exhibited reactive hyperplasia. None of these 52 biopsies were positive for measles virus.

20 Of the 10 control colonoscopic biopsy series, blinded histological examination confirmed normal appearances in 5 of Of the remaining 5 cases, small focal these cases. collections of subepithelial chronic inflammatory cells were 25 found in one case, one case showed mild focal neutrophil infiltration of the lamina propria, while the 3 remaining cases, one of which turned out to be from a child with ulcerative colitis in remission, had reactive follicular hyperplasia of the terminal ileum. Only one control biopsy 30 stained positively for measles virus; that of the child with the ulcerative colitis, in whom a germinal centre in a focus of ileal lymphoid nodular hyperplasia stained in an identical pattern to that above.

35 Of the 10 terminal ileal biopsies from children with Crohn's disease, 9 contained a complete lymphoid follicle with its associated germinal centre. Two cases exhibited severe

inflammation while the remainder showed only mild inflammation, with an increase in lamina propria mononuclear cells but no ulceration. No granulomas were identified in these sections. None of the germinal centres were positive from measles virus. In only one case was a positive signal obtained - in a single endothelial cell.

None of the tissues from either the affected children or the positive or negative controls showed evidence 10 immunostaining for mumps, adenovirus or Herpes simplex virus. Only those lymph nodes from HIV-positive individual with AIDS exhibited positive immunostaining with the HIV primary antibody: characteristically, this was confined to follicular dendritic cells. Rubella antibody produced focal positive 15 staining in brain tissue from a case of congenital rubella syndrome and some non-specific staining was seen occasionally in the laminar propria of both normal and diseased intestine. Each antibody gave a signal that was appropriate for its respective target antigen in infected positive control cells 20 and/or tissue. No signal was seen in sections treated with either corresponding normal serum or without respective primary antibody.

#### Detections of Viral RNA

25

(

The RNA from the peripheral blood mononuclear cells (PBMC) of fourteen children with RBD was analysed for the presence of both measles virus H and N gene RNAs. Negative controls were used consisting of RNA from both uninfected human umbilical vein endothelial cells (HUVEC) and a rat hepatoma cell line.

: In the affected children 5ml of blood was taken in EDTA tubes and PBMC was isolated on ficoll density gradient. Cells were wash in PBS, pelleted, and stored at -70°C until RNA extraction.

Total RNA was extracted from coded PBMC samples using an acid guanidinium phenol-chloroform method. The RNA pellets were washed twice with 70% ethanol, resuspended in 30µl of water and stored at -70°C. Thereafter 100ng of total RNA from PBMC 5 was used in a combined RT-PCR reaction using rTth DNA polymerase and EZ buffer with primers U1A1 and U1A2 according to the manufacturer's instructions. Forty thermal cycles were performed using the following cycling parameters. mixtures were incubated at 68°C for 30 min followed by a 10 denaturation step of 95°C for 3 min. Reactions were then subjected to a further forty thermal cycles of 95°C for 1 min and 58°C for 1 min. After a final extension at 60°C for 7 min, the reaction mixtures were cooled and  $10\mu l$  of PCR product electrophoresed on a 1.2% agarose gel. PCR products were 15 visualised under ultra violet light and transferred to our Hybond-N membrane. Southern hybridization was also performed on the membrane using a 32P-labelled internal oligonucleotide probe (U1A). Positive bands were extracted from agarose gel using butanol. Direct sequencing of amplification products 20 was carried out using a Taq Dye Primer sequencing kit and analysed using a 373AA DNA sequencer.

Measles virus H gene, but no N-gene cDNA was amplified from duplicate PBMC-RNA samples from 6 of the 14 affected children 25 (sequence data from 3 of these children plus one case of Crohn's disease and one case of ulcerative colitis and controls are shown in Figure 1). One children whose biopsy was positive for the N-gene using PCR also stained positive for the measles virus N-protein antigen. Sequence analysis 30 of the amplification product showed it to be consistent with Schwarz vaccine-strain measles virus. Measles H and N gene . cDNAs were also amplified from measles virus infected HUVEC but not from either PBMC-derived RNA from the 6 cases of SSPE or any of the negative controls. Sequence data from RNA 35 derived from 6 brain tissues affected by SSPE are included in Figure 1.

#### Detection of Viral Antibodies

35

Serum samples from 22 children affected with ileo-colonic lymphoid nodular hyperplasia, regressive development disorder 5 and non-specific colitis were compared with 32 control children. The control group consisted of 13 normal children and 19 paediatric patients admitted for routine surgery. Males predominated in the control group and all children were under 10 years of age. For all but one of the affected children and all controls, none had been re-vaccinated against measles.

CSF samples were available from 6 of the children with the syndrome. Serum and CSF IgG and IgM antibody immunoreactivity to measles, rubella, mumps viruses and cytomegalovirus (CMV) was examined by ELISA according to the manufacturer's instructions. For IgM assays, all samples were pre-treated to absorb IgG and Rheumatoid Factor. In order to exclude a non-specific polyclonal elevation in either IgG or IgM, total serum IgG and IgM levels were measured in affected children. All samples were analysed in duplicate, in parallel with standard positive and negative control sera.

The mean measles virus IgG immunoreactivity, as detailed in 25 Table 1, was 4090(SEM±846) MIU/ml for affected children and 2005(SEM±329) MIU/ml for the controls. The difference between the means is statistically significant (p=0.02). values for rubella mean difference in immunoreactivity was not statistically significant when (59{SEM±18}IU/ml) controls children and 30 affected  $(462{SEM\pm9}IU/ml)$  were compared (p>0.4). Neither serum measles nor rubella IgM immunoreactivities were elevated. Measles and rubella IgG and IgM antibodies were undetectable in CSF samples from affected children.

The IqG immunoreactivity for mumps virus and cytomegalovirus

were also ascertain in the affected and control children. The results are detailed in Table 1.

In order to exclude a non-specific IgG response, the specific IgG 5 relationship between measles virus immunoreactivity and total IgG concentration was examined in Using logistic regression, children. statistically significant relationship was observed (p>0.7). addition, there was no statistically significant and rubella IqG measles IqG 10 relationship between immunoreactivities in affected children (p>0.4).

Table 1

|    |                | Serology    | (Mean ± SEN | 1)      |            |
|----|----------------|-------------|-------------|---------|------------|
| 15 |                | Measles     | Mumps       | Rubella | CMV        |
|    | Affected cases | 4090 (±846) | 699(±169)   | 59(±18) | 3 positive |
|    | Control cases  | 2005 (±329) | 723 (±156)  | 46 (±9) | 7 positive |

#### Immunocytological Profiles

Peripheral blood samples from a total of 12 affected children were analysed for total lymphocyte count (CD3), helper T cells (CD4), cytotoxic/suppressor T cells (CD8), B cells (CD19), and

natural killer cells (CD16). CD4:CD8 ratios were also analysed. In the 12 children all but one showed some degree of immunodeficiency, as defined by low numbers of circulating immune cells. All data are age-adjusted.

|   | NK             | 10       | 0.11              | 0.01-0.21         | 0.3-0.7           | 0.08-0.90         |  |

The above tabulated data in Table 2 suggests that children with colitis and regressive developmental disorder have an acquired immunodeficiency in addition to persistent measles virus infection of ileal lymphoid tissue.

The pattern of measles virus immunostaining was quite distinct from that observed previously in Crohn's disease, where it was restricted to macrophages and endothelial cells in foci of granulomatous inflammation. The absence of staining in the ileal lymphoid follicles in both Crohn's disease and other control tissues indicates that in the present case of lymphoid nodular hyperplasia, the reaction is not only specific, but may also represent a novel pathogenic mechanism for measles virus. An influence from both the above clinical and virological data appears to be that either the vaccine strain of the measles virus, or its associated antigens, are capable of persisting within intestinal tissue.

#### Example 5

The gene sequences of vaccine and wild-type measles virus H 30 region were determined using known methods and the majority consequences sequence of the measles virus H region sequences

using all wild-type and vaccine strain sequences for GenEMBL on 1 June 1994 was also determined, as shown in Figure 1. These sequences were then compared to the gene sequence of the H region of measles virus isolated from patients with Crohn's disease, ulcerative colitis and autism, as shown in Figure 1. As the sequences show two of the patients, one with ulcerative colitis and the other with autism had the same single amino acid mutation at base 8419 as the vaccine (Schwarz). None of the patients had exactly the same gene sequence as the majority consequences sequence or any of the sporadic wild strains. As shown in Figure 1 the same sequence of the H region was also compared with the gene sequence of measles isolated from IBD patients with SSPE strains.

#### Claims

- A method for the diagnosis of Regressive Behavioural Disease (RBD) from a body derived sample, which method
   comprises performing an assay for persistent MMR infection in said sample.
- 2. A method according to claim 1 wherein the assay is performed for detection of persistent wild or vaccine mediated 10 measles virus in affected material.
  - 3. A method according to either of claims 1 or 2 wherein the assay comprises the detection of a viral antigen, viral RNA, or viral antibodies.

4. A diagnostic composition adapted to perform a method as claimed in any one of claims 1 to 3.

5. A pharmaceutical composition for the treatment of RBD which composition comprises a soluble dialysed leucocyte extract comprising an MMR antigen specific transfer factor formed by the dialysis of an MMR virus-specific lymphocyte to a molecular weight cut-off of 12,500 in a pharmaceutically acceptable carrier or diluent therefor.

6. A composition according to Claim 5 wherein the MMR virus comprises persistent measles virus.

- 7. A composition according to either Claims 5 or 6 wherein the composition is adapted for subcutaneous, intra-muscular or intravenous injection, or for administration via the oral route, by suppository or by incorporation into liposomes.
- 8. A pharmaceutical composition substantially as hereinbefore 35 set forth, with reference to and/or as illustrated in, the accompanying drawings:

15

25

- 9. A method for the diagnosis of RBD substantially as hereinbefore set forth with reference to and/or as illustrated in, the accompanying drawings.
- 5 10. A diagnostic for the detection of RBD substantially as hereinbefore set forth, with reference to and/or as illustrated in, any one of the accompanying drawings.
